

Clearing Console & Variable Naming

Brief Overview

This note covers [JavaScript Console & Variable Naming](#) and was created from an [uploaded document](#). It covers console clearing shortcuts, cache reset steps, variable naming rules, camelCase conventions, and [best practices](#).

Key Points

- Learn how to clear the console on both Mac and Windows.
 - Understand the steps for emptying cache to reset variables.
 - Review JavaScript naming rules and camelCase usage.
 - Follow concise best-practice guidelines for readable code.
-

Clearing the Console

- **Mac:** Hold **⌘** (Command) and press **K**.
- **Windows:** Hold **Ctrl** and press **K**.
- This shortcut only clears the visible console output; **it does not erase any data stored in the browser** (e.g., previously defined variables).

Clearing Cached Data

- **Mac:** Click-and-hold the **Reload** button → choose *Empty Cache and Hard Reload*.
- **Windows:** Right-click the **Reload** button → select *Empty Cache and Hard Reload*.
- Result: All cached scripts and data are removed, so previously defined variables become **undefined**.

Variable Naming Rules

- Meaningful names make code readable and maintainable.
- Even though JavaScript permits many naming styles, good practice helps teammates (or future you) understand the purpose of each variable.

Common Rules

Rule	What is allowed?	Example (valid)	Example (invalid)
Meaningful name	Descriptive identifier	myName, userAge	x1, data (if unclear)
Reserved keywords	Cannot be used alone as a variable name	—	var
Contain keywords	Allowed if part of a longer name	myVar	—
Start with a number	Not allowed	—	123name
Contain numbers	Allowed after the first character	my123	—
No spaces	Variable name must be a single token	myName	my name
Allowed characters	Letters, digits, \$, _	price\$, _count	my-name, price%

Camel Casing

CamelCase: A naming convention where the first word starts with a lowercase letter and each subsequent word begins with an uppercase letter (e.g., myVariableName).

- **Why use camelCase?**
 - Prevents ambiguous reading such as *TherapistFinder.com* → *The rapistFinder.com*.
 - Provides a consistent visual cue across the codebase.
- **Pattern:** lowercaseWord + UppercaseWord + UppercaseWord...

Summary of Best Practices

1. Choose **clear, descriptive names** that convey the stored data's purpose.
2. Avoid JavaScript **reserved keywords** as standalone variable names.
3. Begin names with a **letter, \$ or _**, never a digit.
4. Use only **letters, numbers, \$ and _**; no spaces or other symbols.
5. Adopt **camelCase** for all variables to maintain consistency and readability.
